

Shallow substrate texture — supported zones are COARSER, opposite to the predicted fine-sediment direction

Source: SoilGrids v2.0 (ISRIC), 250 m, sampled on the native grid — a shallow soil-texture SURROGATE, not a geological map. It samples the upper ~2 m only and does not observe the compaction interval; lithology, formation and age are not identified. Supported zones carry -5.0 pp less clay and +6.4 pp more sand than controls. H005 is shown for completeness and is not part of the supported/control contrast. Deep geological / aquifer-system susceptibility is NOT ADEQUATELY TESTED, not exonerated.
