

All four classification zones are heavily built — a shared setting that cannot explain selectivity

Source: ESA WorldCover 2021 (10 m) and JRC GHSL GHS-BUILT-S E2020 (~93 m); polygons rasterised on each SOURCE grid, never resampled to 40 m.

H001 and H002 rank differently between the two products — a discriminator that flips sign between independent datasets is not robust.

GHSL 2020→2025 built-up change is exactly zero at H001–H004. Post-2020 GHSL epochs are projections, not observations, so this is an absence of detected change rather than a measured absence. Built fraction describes the common setting; it does not separate the supported zones from the controls. No loading is estimated here.
